

Hip Joint with Pelvic Band and Belt Suspension

The hip joint with pelvic band and belt suspension is used with transfemoral (above knee) prostheses. This style of suspension provides rotational control and mediolateral (side to side) stability of the pelvis (hips). It works best for patients who are obese or for those who have a large amount of redundant tissue that is difficult to stabilize. This suspension can also be effective for patients who have weak abductor muscles.

Modern Technology. Traditional Values. Proven Techniques.
