

Multi-Durometer Insert

The multi-durometer insert is made of two types of material. (Durometer is a way of measuring the hardness of a material.) Usually the material next to the patient's skin is made of a soft durometer to cushion the residual limb. The outer layer is a firm durometer material that makes the liner more durable for normal wear and tear. This style of insert is used by patients who require a soft insert because of their tissue type, but need durability for their activity level.
